Iteration 0

Golden Hours Survival Rate

De Guzman, Aero Kent
Frederick Masangkay

Iteration 1

Problem Identification

The availability of some care services are not always accessible by people around the Philippines in terms of distance. Because of this the survival rate of some patient decreases due to the distance required to travel to a further care center.

Decomposition

- The geographical location of an individual.
- The type of illness that a person may have
- The medium of transportation used to travel to their destination.
- A persons background, whether a civilian or an ambulance driver

Pattern Recognition

The distance required poses a threat when it comes to the survival of an patient.

Abstraction

Relevant : Illness, Distance, Transportation
Irrelevant :

- Situation of the road, whether traffic or not.

Graphic Organizer

Iteration 2

Problem Identification

How will I be able to get the least distance required in order to get to a care center?

Decomposition

- How to utilize the total distance to figure out the survival.

Pattern Recognition

To get the least distance required, simply use an algorithm that can disseminate a given list in order to figure out the list distance among them. But what possible algorithm can be used?

Abstraction

Graphic Organizer

Iteration 3

Problem Identification

The dijkstra algorithm can be used in combination to using nodes to simulate the roads to obtain the least distance and dynamic programming to both store and utilize the distance and time data, but how can the distance be used to figure out the survival of a patient?

Decomposition

How will you be able to calculate the comparison between the distance and the time.

Pattern Recognition

Utilizing both a given golden hour of an illness can be used to compare the given output of the least distance required.

Abstraction

Code Breakdown

```python
class GoldenTime():
    def __init__(self): # A pre-existing available time is already here
        self.illness = {
            'heart attack' : 3600,
            'stroke' : 21600,
            'trauma' : 3600,
            'asthma attack' : 3600,
            'severe dehydration' : 7200,
            'septic shock' : 3600,
            'dengue hemorrhagic fever' : 86400,
            'severe allergic reaction' : 3600,
            'third-degree burns' : 3600,
            'tetanus' : 7200,
            'severe pneumonia' : 3600,
            'severe malaria' : 43200
            }

    # Simply shows the current data inside the dictionary.
    def show_golden_time(self):
        print(f'\ncurrently stored golden times (name : seconds) : \n{self.illness}')

    # This can be used to insert a new Illness with its corresponding time on
    # the dictionary, don't mind this if you are not the user since you will
    # actually need to edit the dictionary directly if you want to save it for
    # later use...
    def add_golden_time(self):
        while True:
            try:
                ill  = str(input('\nPlease input the name of the illness : '))
                time = int(input('Please input the Golden Time in SECONDS of the illness : '))
                break
            except ValueError:
                print('PLease insert the time in whole integers!')
        ill = ill.lower()
        self.illness[ill] = time
        print(f'updated [{ill} : {time}] to the dictionary.')
        self.show_golden_time()
```

```python
    # simply calculates whether some common possible illnesses in the philipp
    # survivable with the given distance both in the minimum and maximum spee
    # compared to its golden hour expressed in seconds.
    def golden_survival(self, min_distance):
        min_speed    = round((min_distance / 16.67), 4) # m/s
        max_speed    = round((min_distance / 27.78), 4) # m/s
        print(f'\n{min_speed} seconds is the amount of time it will take goir
        print(f'{max_speed} seconds is the amount of time it will take going
        for i in self.illness:
            print(f'\nTesting {i}\n')
            min_survival = True
            max_survival = True
            if self.illness[i] < min_speed:
                print(f'{i} FAILED the minimum speed')
                min_survival = False
            else: print(f'{i} PASSED the minimum speed')
            if self.illness[i] < max_speed:
                print(f'{i} FAILED the max_speed')
                max_survival = False
            else: print(f'{i} PASSED the minimum speed')
            if min_survival == True and max_survival == True: print(f'{i} passed both test!')

        if min_survival == True and max_survival == True: print('\nall common illnesses are survivable!')
        else: print('\nthere were some illnesses that failed either or both minimum and maximum speed.')
```

Code Breakdown

```python
SimulatedRoads = { # Distances of each node from their adjacent nodes.
    'A' : [('B', 100), ('C', 150), ('D', 800)],
    'B' : [('A', 100), ('C', 250), ('E', 350)],
